The following report is presented in partial fulfillment of the requirements for the Master of Arts degree in Economics, at Kansas State University.

The subject-matter of the paper was chosen because of its relation to economic development which will be one of the fields of interest of the author in pursuing further graduate study.

The first chapter contains a short discussion on inequality, what it means, and the possible ways of measuring inequality. The specific measures used in the report to examine inequalities in gross national product and trade among countries is discussed in detail.

In the second chapter a study is made of the inequalities in the world distribution of gross national product, exports, imports and total trade for the period, 1950 to 1962. An attempt is made to assess the trends and examine the changes in inequalities over this period.

In the third chapter emphasis is switched to the divergency between the developed and the less developed countries. An examination is made of the changes in inequalities between the developed and less developed countries. The countries are then grouped according to per capita incomes and a study is made of the changes in inequalities which have taken place over this 1950-1962 period. These groups are also compared with the United States over this same period.

In the fourth chapter a study is made of the changes in inequality among different regions of the world. These regions are the English Speaking and European countries, Latin America, Middle East, Asia and Africa. An attempt is also made to examine the inequalities in gross national products and trade among the countries within these groups. The fifth and final chapter presents a summary of the findings of the report.

The assistance and guidance by Dr. G. V. L. Narasimham, of the Department of Economics, Kansas State University, is gratefully appreciated. His guidance was very helpful throughout the process of compiling and analyzing the data. The discussions with other members of the Department of Economics were helpful.

INTRODUCTION

This is a study, primarily empirical in nature, of international trade and the changes which have occurred in the distribution of gross national product, exports and imports over the period from 1950 to 1962. The study includes eighty-five free market countries which are members of the United Nations.

The problem of inequality in the distribution of income and trade among countries has received much attention in the last fifteen years.¹ This is especially true with respect to the purported divergency of income and trade between the developed and the less developed countries. It is the major contention of some economists that this gap is large and increasing.²

This has prompted a number of proposals for narrowing this gap such as export promotion, import substitution and the granting of trade preferences for the less developed countries. Although much attention has been focused on how to narrow the differences or inequality among countries, very few attempts have been made to examine the actual quantitative aspects of these differences.³

The purpose of this study is to examine the distribution of income and trade to see if the divergence and inequality

¹United Nations, "Towards a New Trade Policy For Development," Report by the Secretary-General of the United Nations Conference on Trade and Development, New York, 1964, p. 4-5.

²Three of the major proponents of this line of thinking is Hans Singer, Gunnar Myrdal and Raul Prebisch.

³One of the best studies is one by Theodore Morgan, "Economic Relationships Among Nations: The Pattern of Commodity Trade", The Economic Ideas of Hankind. Ed. by Berthold Hoselitz (New York: Columbia University Press, 1965).

between the developed and the less developed countries is increasing. An examination of the divergence of income and trade between different regions of the world is also made.

To measure this divergence the income and trade data of the countries was converted into United States dollars at 1960 prices. This provided a standard with which comparisons were made. The Lorenz curve concentration ratio was then used as a measure of inequality. The countries were grouped according to different criteria of development and the divergence and trends in gross national products, exports, imports and trade were examined.

CHAPTER I

MEASURES OF INEQUALITY

Measurement denotes comparison which makes it necessary to consider a norm or standard against which actual inequality might be compared. A prerequisite to measuring inequality in international trade and income among developing countries then is to establish what is meant by equality. It probably isn't correct to assume that each country or each proportion of the population should have the same proportion of income, exports or imports. Although this might seem desirable from a moral standpoint, it is beyond the realm of feasibility. Each country has certain characteristics which dictates a proportionate equality. Proportionate equality means that the division of income and trade is determined by the factor endowments of the countries as well as the initiative of the people, geographic location, and numerous other things. For example, the United States is geographically located in an environment conducive for agriculture production, while the Soviet Union's location is less suitable for agriculture production. This is a fact and this is an example of factors which determine the proportional equality. The extent of this proportionality would be difficult to establish under any circumstances even for only a small number of countries.

No attempt has been made to devise this type of measurement; however, some insight to the situation can be gained from describing degrees of inequality in terms of deviations from the

equalitarian ideal.⁴ Therefore, any norm may serve as a theoretically useful standard for factual comparisons. This very conveniently allows examination of changes which have taken place over a period of time. There are a number of measures of inequality each having certain advantages as well as disadvantages.

The Pareto Coefficient

One of the earliest measures of income inequality was introduced by Vilfredo Pareto in 1897. This measure consisted of plotting, on double-logarithmic paper, the size of an individual's income against the number of income receivers having that income or larger.⁵ Pareto's formula was $\log N_x = K - \alpha \log X$ where N_x is the number of income recipients with an income of X or greater and K and α are constants.⁶ It implies that plotting N against X on double-logarithmic paper gives a straight line with a slope α . This α is the coefficient of inequality. Pareto's measure emphasized the upper part of the income distribution and thus failed to consider the character of the rest of the distribution. This failure to consider the whole distribution results in an inadequate measure of the degree of inequality.

⁴Alker, Hayward R., Mathematics and Politics (New York: The Macmillan Company, 1965), p. 36.

⁵Bowman, Mary J., "A Graphical Analysis of Personal Income Distribution in the United States", American Economic Review, Vol. XXXV, September, 1945. p. 615.

⁶Kravis, Irving B., The Structure of Income (Washington, D.C.: McGregor and Werner, 1962), p. 180.

The Coefficient of Variation

The normal frequency distribution suggests that the most frequent occurrence of the characteristic is the average one. A common measure of dispersion, or inequality, is the standard deviation. Assume f_i represents the frequency and Y_i the mean income in an income class and \bar{Y} the mean income of the entire distribution. Using this notation the standard deviation (σ) for grouped data may be approximated by

$$\sigma = \sqrt{\frac{\sum f_i Y_i^2 - \bar{Y}^2}{\sum f_i}}$$

where the summations are over the data subclasses.⁷ This measure may be standardized by dividing it by the mean of the variable being studied. This reduces its dependence on the measurement units being used, giving what is called the coefficient of variation.

Despite their statistical properties, these two measures suffer from two difficulties not found in alternative measures of inequality, such as the mean deviation or concentration ratio. First, average squared deviations from a mean are not easily understood by the nonstatistician especially if a normal frequency distribution cannot be assumed. Secondly, such measures

⁷Ibid. p. 181

are sometimes sensitive to the way in which the more extreme data points are grouped.⁸

Shares by Quantization

This method of measuring inequality considers the entire distribution presented in terms of the proportion of the total distribution accruing to equal segments such as tenths, fifths or fourths.⁹ Advantages of this procedure is that it avoids making a single summary measure. However, in some instances this can be a major disadvantage, since it tends to complicate the process of comparison. It lacks the one statistic measure which facilitates comparison.

A more extreme measure of a distribution is to consider the percentage of the total held by a given top percent of units. This type of measurement is often used in studying business concentration.

The Lognormal Distribution

The lognormal distribution may be defined as the distribution of a variate whose logarithm obeys the normal law of probability.¹⁰ The lognormal distribution has been used as a

⁸Yntema, D., "Measures of the Inequality in the Personal Distribution of Wealth", Journal of American Statistical Association, Vol. XXVIII, 1933, p. 429.

⁹Kravis, 178.

¹⁰Aitchison, J. and Brown J.A.C., The Lognormal Distribution (Cambridge: University Press, 1957), p. 1.

statistical description of given data in measuring inequality.¹¹

Sometimes the logs of data conform more closely to a normal distribution than does the data in natural numbers. This suggests that the standard deviation of the logs might be a better evaluation of differences in various distributions. This would be true in comparison with the standard deviation and coefficient of variation of natural numbers.

The Lorenz Curve Concentration Ratio Principle

The Lorenz Curve was first discussed in 1905 by M.C. Lorenz. Since that time it has become a very useful device for measuring inequality.¹² This measure compares cumulative distributions with theoretically determined norms. The Lorenz type diagram allows for both visual and quantitative comparison of the cumulative relationship between two variables with the overall arithmetic mean relationship. The axes of Lorenz diagrams are measured in percentages which facilitates summary description at other periods and with other groups of data. Another attractive feature is that it represents a summary description by a single value measure which is convenient for comparing particular facets of different curves.

¹¹Ibid. p. 107.

¹²Lorenz, M.C., "Methods of Measuring Concentration of Wealth" Publications of the American Statistical Association, Vol. II (New Series 1905) p. 209.

Figure 1

The Lorenz Diagram

Quantitative comparisons involves computation of the concentration ratio. The concentration ratio is the ratio of the area of actual concentration to the area of maximum possible concentration. In Figure 1 this would be the area enclosed between the Lorenz curve and the line of complete equality (OMQ), expressed as a ratio of the area of the triangle (OPQ). This measure owes its discovery to the work of Corrado Gini in several articles published in 1912.¹³

¹³Hainsworth, G.B., "The Lorenz Curve As a General Tool of Economic Analysis," Economic Record, September 1964, p. 429.

Use of the Lorenz type diagram along with the concentration ratio has led Mahalanobis to the use of the concentration curve principle to compute an index of concentration.¹⁴ Adapted to this analysis the concentration curve measures the percentage of countries along one axis against the corresponding lowest percentage of gross national product, exports or imports on the other axis. Thus the curve itself is absolutely independent of units of money or of quantity and is readily comparable with concentration curves for different groups in different time periods.

For this analysis the whole distribution of k countries gross national products, exports and imports is taken. Let f_j denote the countries and e_j the gross national product, exports and imports of these f_j countries, ($j = 1, 2, \dots, k$). Let P_j and Q_j be the proportions of countries and total gross national products, exports or imports in the j th class respectively.

Then
$$P_j = \frac{f_j}{N} ; \quad Q_j = \frac{e_j}{E}$$

where $\sum f_j = N$; $\sum e_j = E$ which are respectively the total number of countries and the total gross national products, exports or imports in the entire population or world. Let p_i and q_i be the cumulative proportions

¹⁴Murti, V.N. and Pillai, K.M.C., "Distribution of Population By Expenditure Glasses," Central Statistical Organization, September 1960.

defined as

$$p_i = \sum_{k=1}^i p_k ; \quad q_i = \sum_{k=1}^i q_k.$$

The set of points (p_i, q_i) together with $(0,0)$ and $(1,1)$ determines the concentration curve of the total gross national products, exports, or imports. The index of concentration is approximately given by

$$I = 1 - \sum_{i=0}^k (p_i - p_{i-1}) (q_i + q_{i-1}).$$

This is the procedure followed for all calculations of inequality throughout this paper.

CHAPTER II

CHANGES IN INEQUALITY OF THE WORLD DISTRIBUTION OF GROSS NATIONAL PRODUCT EXPORTS, IMPORTS AND TRADE, 1950-1962

Economic progress among nations denotes economic growth. All nations seek to obtain a larger amount of goods and services for their growing populations. This larger amount of goods is usually the result of increased production supplemented by international trade.

International trade has made a tremendous contribution to the development of all countries. It enables each country to specialize and to export those things that it can produce cheaper, in exchange for goods which other countries may have a comparative advantage in producing. This tends to increase the goods and services available to the people within those countries, along with increasing national income and hopefully equalizing the living standards. It is this equality of income and trade that is the major concern of this paper. The major interest of this chapter is the changes in inequality of the world distribution of gross national product, exports, imports and total trade for the period, 1950-1962.¹⁵

¹⁵The use of the word world distribution seemed justified, since the eighty-five countries in the study contains the major portion of world income and trade.

Trends in the Volume of Trade
Gross National Product and Population

Examination of the statistics shows that the world economy has experienced substantial growth. Table 1 contains indices showing the growth of trade, income and population.¹⁶ The total

TABLE 1. -- The secular trend in the volume of trade, gross national product and population (1950=100)

	1950	1954	1958	1962

Total GNP	100	119	138	160
Total Population	100	104	112	120

volume of trade of the eighty-five free market countries examined, more than doubled over the thirteen year period 1950 to 1962. Over this period total trade, which is the sum of exports and imports, rose 6.2 percent a year. During this same period gross national product rose 4.0 percent a year, while population was growing at the rate of 1.5 percent a year. These facts give a rough indication that there has been substantial progress made

¹⁶ The source of all the data used throughout this report was the United Nations Yearbook of National Accounts Statistics, (various issues). The data was then converted into United States dollars at 1960 prices.

in the world economy both with respect to income and trade. However, further insight to the situation can be gained by examining the distribution of gross national product and trade among the countries.

Distribution of Gross National Product

Each country's share of world gross national product, exports, imports and total trade was taken and arranged in ascending order and grouped by quintiles (Table 3). This was done for the years 1950, 1954, 1958 and 1962. Since the complete analysis of this chapter is based on the ascending cumulative distributions of gross national products, exports, imports and total trade grouped by quintiles of countries, it first becomes advantageous to consider the composition of these quintiles. This is important for purposes of comparison. It would facilitate comparison if the countries comprising the lowest quintile of gross national product, exports, imports or trade could consistently be classified as one type of country.

Computation of the rank correlation coefficients between gross national products and exports, imports and total trade are shown in Table 2. The high rank correlation coefficients obtained indicates that there is a close association between countries with a large gross national product and countries with large exports, imports, or total trade over this period. Given this and assuming that generally countries with a high gross national product have the higher per capita products, comparisons can be made differentiating to some degree between the developed and less

TABLE 2. -- Rank Correlations between gross national product and exports, imports and total trade.

	GNP/Exports	GNP/Imports	GNP/Total Trade
1950	.938	.940	.950
1954	.920	.954	.949
1958	.932	.946	.947
1962	.934	.958	.947

developed countries. This would seem particularly true in reference to comparisons of the top and lowest quintiles of countries.

Examination of the statistics for gross national product in Table 3 reveals some interesting facts. The countries making up the lowest quintile are those with the lowest 20 percent of gross national product. These countries had 0.41 percent of the total gross national product in 1950 and 0.42 percent in 1962. This means that the lowest quintile of countries has maintained their share of gross national product over the period. The second quintile of countries share of world gross national product increased from 0.95 percent in 1950 to 1.18 percent in 1962. The third quintiles share rose, as did the fourth quintiles share of gross national product. The rise in the share of world gross national product of the four lowest quintiles of countries was at the expense of the top quintile of countries. This clearly indicates that there has been a slight decline in inequality among countries in the overall distribution of gross national product.

TABLE 3. -- Distribution of world gross national products, exports, imports and total trade by quintiles of countries.^a

	SHARES BY PERCENTAGE				
	<u>Lowest quintile</u>	<u>Second quintile</u>	<u>Third quintile</u>	<u>Fourth quintile</u>	<u>Top quintile</u>
<u>1950</u>

Total Trade	.95	2.37	5.64	13.50	77.54

^aSource: Derived from Appendices I and II.

Visual evidence of this decline in inequality can be seen from examining Figure 2 of the concentration curve in Plate I. Figure 2 shows that the four lowest quintiles of countries had a larger share of the gross national product in 1962, while the top quintiles share was slightly less.

A more refined quantitative measure of the changes in inequality can be made through the use of the index of concentration. Table 4 contains the indices of concentration for the world distribution of gross national product, exports, imports and total trade.

TABLE 4. -- Index of concentration for the world distribution of gross national product, exports, imports and trade.^a

	GNP	Exports	Imports	Total Trade

1958	.842	.749	.726	.736
1962	.836	.739	.722	.729

^aSource: Derived from Appendix II.

EXPLANATION OF PLATE I

Fig. 2. The lower part contains the concentration curves for the world distribution of gross national product for 1950 and 1962. The upper part contains the concentration curves for the world distribution of total trade for 1950 and 1962.

Fig. 3. The lower part contains the concentration curves for the world distribution of exports for 1950 and 1962. The upper part contains the concentration curves for the world distribution of imports for 1950 and 1962.

PLATE 1

The concentration index decreases from 0.846 in 1950 to 0.836 in 1962. The general trend over the thirteen year period can be seen in Figure 4. It is clear that there hasn't been an

Fig. 4. -- Trends in the inequality of gross national products and total trade for 1950-1962.

increase in equality in the distribution of gross national product. In fact there has been a slight downward trend in inequality.

Distribution of Exports and Imports and Total Trade

The downward trend in overall inequality which was present in the distribution of gross national product was not present in the distribution of trade. However, there was no significant increase in inequality in the distribution of trade. In fact, the two lowest quintiles of countries increased their percentage share of trade slightly over the thirteen years, (Table 3). The third and fourth quintiles experienced a decline in their percentage share of trade over this period. The most significant change was in the top quintile, which increased its share from 75.29 percent in 1950 to 77.54 percent in 1962. Visually this can be seen from viewing the concentration curves in Figure 2. The index of concentration (Table 4) increases from .721 in 1950 to .729 in 1962. The trend in inequality for the distribution of trade can be seen in Figure 4. This reveals that there has been little change over the thirteen year period.

The trend and pattern of trade becomes clearer when examining the distribution of exports and imports of each quintile. Table 3 shows that the percentage of exports and imports for both of the lower quintiles increased, but the percentage increase in imports was larger. The third quintile experienced a decline in percentage of both exports and imports, but there was a greater decline in the percent of exports. The fourth quintile held a constant percentage of exports but had a decrease in the

share of imports from 15.35 percent in 1950 to 14.13 percent in 1962. The top quintile increased its percentage of both exports and imports.

Visual evidence of those changes in the distribution of both exports and imports can be seen in Figure 3. As a result of those changes the index of concentration increased slightly from .730 and .716 in 1950 to .739 and .722 in 1962 for exports and imports respectively, (Table 4). However, as explained above these changes weren't at the expense of the two lowest quintiles of countries in either exports or imports. Since it has been shown that the total volume of trade, exports and imports increased and that the lower quintiles maintained and even increased their share of the total trade, exports and imports, then it follows that there has been no deterioration in the shares of trade, exports, and imports going to the two lowest quintiles. This far only the overall distributions of shares of total gross national product, exports and imports has been considered. To examine the importance of trade in the world economy it becomes necessary to relate it to some form of economic activity.

International Trade and Its Importance in Economic Activity

Table 1 shows that an increase has taken place in the total volume of trade. However, to obtain the true character of this increase in the volume of trade, it becomes necessary to make a comparison with some phase of economic activity such as total

gross national product. This gives an idea of the importance of international trade and whether countries are becoming more or less independent in the world economy.

Table 5 shows total world trade as a proportion of total world gross national product. It is clear that, along with an

TABLE 5. -- Total world trade as a proportion of total world gross national product.^a

	1950	1954	1958	1962
Ratio of total trade to GNP	19.5%	20.7%	22.8%	24.8%

^aSource: Derived from Appendix I.

increasing total volume of trade, there has been an increase in the importance of trade. Total trade as a proportion of total gross national product increased from 19.5 percent in 1950 to 24.8 percent in 1962.

A more refined comparison can be made by examining exports, imports and total trade as a proportion of gross national product of each quintile of the countries. This has been done in Table 6.

Table 6 shows that the pattern of increasing importance of trade to gross national product is true for each quintile of countries. It also shows that the ratio of trade to gross national product is largest for the countries in the lowest quintile and decreases slightly for each higher quintile. This means that trade has become increasingly more important to the

TABLE 6. -- Exports, imports and total trade expressed as a proportion of gross national product of each quintile of countries.^a

	<u>SHARES BY PERCENTAGE</u>				
	<u>Lowest</u> <u>quintile</u>	<u>Second</u> <u>quintile</u>	<u>Third</u> <u>quintile</u>	<u>Fourth</u> <u>quintile</u>	<u>Top</u> <u>quintile</u>
Ratio to GNP of					
<u>1950</u>					
Exports	21.6	19.7	22.7	17.4	8.5
Imports	20.5	24.2	21.7	18.6	8.2
Total Trade	44.2	47.4	44.5	36.1	16.7
<u>1954</u>					
Exports	23.0	18.3	21.7	17.2	9.3
Imports	29.0	28.4	22.8	18.2	8.8
Total Trade	53.6	47.8	44.6	35.3	18.0
<u>1958</u>					
Exports	21.6	19.8	22.1	17.2	10.3
Imports	28.9	25.4	25.8	18.2	10.0
Total Trade	50.2	47.2	48.3	35.1	20.4
<u>1962</u>					
Exports	27.9	23.1	23.2	20.7	10.9
Imports	33.9	28.5	26.4	21.0	10.8
Total Trade	56.2	49.9	47.0	39.9	22.1

^aSource: Derived from Appendices I and II.

the countries in the lower quintiles themselves. However, this doesn't mean that the countries in the lower quintiles have experienced a larger absolute share of total trade. Table 7 gives the secular trend in the absolute value of trade, exports and imports for each quintile over the period, 1950-1962.

TABLE 7. -- Secular trend in absolute value of trade, exports and imports for each quintile.

(1950 = 100)		
Trade	1950	1962
Lowest quintile	100	214
Second quintile	100	214
Third quintile	100	175
Fourth quintile	100	192
Top quintile	100	215
<hr/>		
Exports		
Lowest quintile	100	218
Second quintile	100	239
Third quintile	100	169
Fourth quintile	100	206
Top quintile	100	209
<hr/>		
Imports		
Lowest quintile	100	278
Second quintile	100	240
Third quintile	100	201
Fourth quintile	100	195
Top quintile	100	215

The absolute value of trade of the two lowest quintiles increased 2.14 times while the top quintile increased 2.15 times over the thirteen years. This indicates that the lowest and highest quintiles has maintained a constant share of trade over the period. This tends to confirm investigations made earlier

indicating the percentage shares of the highest and lowest quintiles has remained fairly constant.

The absolute value of trade of the third and fourth quintiles increased 1.75 and 1.92 times respectively. This is compatible with earlier evidence indicating that the gains of the lowest, second and top quintiles was at the expense of the third and fourth quintiles.

The countries in the lowest quintile had a ratio of exports to gross national product of 21.6 percent in 1950, while this same ratio for 1962 was 27.9 percent, (Table 6). This indicates that exports as a proportion of gross national product has increased; however, this same comparison for imports shows that imports have increased even more and is a larger proportion of gross national product than exports. Table 7 indicates that the absolute value of exports increased 2.18 times, while imports increased 2.78 times. Thus, it is clear that imports is a larger proportion of gross national product than exports and that this increase in imports is the reason the lowest quintile has maintained a constant share of trade over the period. However, it is important to note that this diversion between exports and imports was a result of a faster increase in imports and not a decrease in exports. The fact that the major increase in imports was in the lowest quintile may indicate the importance of imports to the development process. This same pattern was also present in the third quintile of countries. The top and second quintiles maintained a fairly

constant share of exports and imports, while the fourth quintile experienced a decline in the share of imports relative to exports.

The implications of this analysis would indicate that the distribution of trade, exports and imports has exhibited no real unfavorable changes towards the less developed countries over the 1950-1962 period and has in fact exhibited a rather constant change.

CHAPTER III

CHANGES IN INEQUALITY OF GROSS NATIONAL PRODUCT, EXPORTS, IMPORTS AND TOTAL TRADE FOR THE DEVELOPED AND LESS DEVELOPED COUNTRIES

Having examined the overall distributions of gross national product, exports, imports and trade by quintiles of countries, attention is now focused on a more explicit division. The countries were grouped into a group of developed and a group of less developed countries.¹⁷ Appendix III contains a list of this division.

Developed Versus the Less Developed Countries

Table 8 gives the percentages of gross national product, exports, imports and total trade represented by the corresponding percentage of developed and less developed countries. The less developed countries represented 70.4 percent of the countries in 1950 and held 14.5 percent of the gross national product, while in 1962 the less developed countries represented 72.0 percent of the countries and held 15.9 percent of the gross

¹⁷The division between developed and less developed countries was taken from: James C. Ingram, International Economic Problems (New York: John Wiley & Sons, 1966) p. 75.

TABLE 8. -- Distribution of gross national product, exports, imports and total trade between the developed and less developed countries.^a

^bThe reason for the variation in the percentage of developed and less developed countries each year is that there were a few countries for which data wasn't available every year.

national product. The fact that the percentage of the less developed countries changes makes comparison difficult. However, comparisons can readily be made by using the concentration curve and the index of concentration.

Figure 5 of Plate II shows the distribution of gross national product and trade between the developed and the less developed countries for 1950 and 1962. This visual comparison coincides with the results of the index of concentration in Table 9, which shows an index of .559 and .561 in 1950 and 1962, respectively. This means that the inequality in the distribution of gross national product was not significantly greater in 1962 than it was in 1950. However, the index of concentration for 1954 and 1958 shows that there was a slight increase in inequality within this thirteen year period which decreased by 1962.

TABLE 9. -- Index of concentration for the distribution of gross national product, exports, imports and total trade between the developed and less developed countries.

	GNP	Exports	Imports	Total Trade
1950	.559	.482	.474	.478
1954	.575	.509	.488	.498
1958	.577	.535	.506	.520
1962	.561	.524	.517	.520

Figure 5 shows that the inequality in the distribution of total trade has increased slightly over the period. The index

The upper part contains the concentration curves for the distribution of imports between the developed and less developed countries for 1950 and 1962.

PLATE II

Figure 5

Figure 6

of concentration shows that there has been a gradual upward trend in inequality for the distribution of trade.

Figure 6 shows the distribution of exports and imports between the developed countries and the less developed countries. It is visually evident and is quantitatively substantiated by the indices of concentration that there has been a slight increase in inequality in the distributions of exports and imports.

Division of Countries by Per Capita Incomes

A more specific analysis between the developed and less developed countries was made by grouping the countries according to per capita income. The countries were grouped according to their per capita incomes in 1961.¹⁸ Group 1 consisted of countries with a per capita income of less than \$100, group 2 of countries with a per capita income of \$100 - \$250, group 3 of countries with a per capita income of \$250 - \$500, group 4 of countries with a per capita income of \$500 - \$1,000, group 5 of countries with a per capita income of \$1,000 - \$2,000, and group 6 of countries with a per capita income of more than \$2,000. Appendix IV contains a list of the countries in each group.

Table 10 gives the distribution of gross national product, exports, imports and total trade for the per capita income

¹⁸The per capita income classification was adapted from: C. Wilcox, W. Weatherford and H. Hunter, Economics of the World Today, (New York, Harcourt, Brace and Co., 1962) p. 16-18.

TABLE 10. -- Distribution of gross national product, exports, imports and total trade between countries grouped by per capita income classes.^a

	PER CAPITA INCOME GROUPS					
	Less \$100	\$100 \$250	\$250 \$500	\$500 \$1,000	\$1,000 \$2,000	Over \$2,000
	Group 1	Group 2	Group 3	Group 4	Group 5	Group 6
Percentage of total:						
<u>1950</u>						
Countries	16.9	28.2	19.7	15.5	16.9	2.8

Imports	4.6	7.2	8.2	13.6	40.3	26.0
Total Trade	4.8	6.9	8.4	12.7	40.6	26.6
<u>1954</u>						
Countries	17.1	30.3	19.7	14.5	15.8	2.6
GNP	5.4	3.7	7.6	6.8	24.0	52.5
Exports	6.4	5.1	9.2	12.6	41.9	24.8
Imports	7.5	5.1	9.2	13.4	39.8	25.0
Total Trade	7.0	5.1	9.2	13.0	40.8	24.9
<u>1958</u>						
Countries	21.4	28.6	20.2	13.1	14.3	2.4
GNP	5.4	4.3	8.6	7.1	24.2	50.3
Exports	4.5	6.4	10.1	13.7	41.4	23.9
Imports	4.9	8.0	9.9	13.6	39.0	24.5
Total Trade	4.7	7.2	10.0	13.6	40.2	24.2
<u>1962</u>						
Countries	16.0	29.3	21.3	14.7	16.0	2.7
GNP	4.6	3.7	9.8	7.4	24.6	49.9
Exports	3.0	5.8	11.1	15.5	41.5	23.1
Imports	3.8	6.3	10.8	15.4	41.8	21.9
Total Trade	3.4	6.0	11.0	15.5	41.7	22.4

^aSource: Derived from Appendices II and IV.

groups. The concentration curves for these distributions are shown in Figures 7 and 8 of Plate III. By examining these concentration curves it is possible to get an idea of the changes in inequality which have taken place between the groups over the period, (1950-1962).

TABLE 11. -- Index of concentration for the distribution of gross national product, exports, imports and total trade for countries grouped by per capita income classes.

	GNP	Exports	Imports	Total Trade
1950	.712	.507	.504	.505
1954	.703	.541	.525	.533
1958	.695	.559	.535	.547
1962	.685	.539	.527	.532

Table 11 shows that the index of concentration for the distribution of gross national product has decreased from .712 in 1950 to .685 in 1962. This substantiates the earlier finding of a downward trend in inequality when the countries were grouped by quintiles. Figure 7 shows that the major reason for this decrease in inequality is due to the decline in the percentage share of gross national product held by the countries in group 6, which are the United States and Canada.

There was a slight increase in inequality in the distribution of exports, imports and trade, (Figure 8). Countries with a per capita income of less than \$100 represented 16.9 percent of the countries and held 4.8 percent of the total trade while in 1962, 16.0 percent of the countries held only 3.4 percent

EXPLANATION OF PLATE III

Fig. 7. The lower part contains the concentration curves for 1950 and 1962 for the distribution of gross national product of the countries grouped by per capita income groups. The upper part contains the concentration curves for 1950 and 1962 for the distribution of total trade of the countries grouped by per capita income groups.

Fig. 8. The lower part contains the concentration curves for 1950 and 1962 for the distribution of exports of the countries grouped by per capita income groups. The upper part contains the concentration curves for 1950 and 1962 for the distribution of imports of the countries grouped by per capita income groups.

PLATE III

Figure 7

Figure 8

of the total trade. Thus while the earlier study indicated the share of trade of the lowest quintile was constant, this is not the case for the countries in group 1. An examination of the composition of total trade shows that group 1 represents 16.9 percent of the countries and held 4.9 and 4.6 percent of the exports and imports respectively in 1950. In 1962, group 1 represented 16.0 percent of the countries, but held only 3.0 and 3.8 percent of the exports and imports respectively. Thus it would seem that concern over a decline in exports is justified. It is difficult to evaluate the effects of the decline in the percentage share of imports. This decline in imports could mean there had been a major emphasis on the use of import substitution by the countries. However, any extensive development process usually requires large amounts of imports on the part of the less developed countries. Therefore, it would seem that the decline in imports represents a serious obstacle to furthering development of these countries in group 1 with per capita incomes of less than \$100.

This same pattern of a decline in the share of trade is also true for the countries with a per capita income of \$100 to \$250. In this case in 1950, group 2 represented 28.2 percent of the countries which held 6.9 percent of the trade. However, in 1962 a larger percent of countries had a smaller share of total trade.

The other significant change in Table 10 occurred in group 6 which is composed of the United States and Canada. Group 6

represented 2.8 percent of the countries which held 26.6 percent of total trade in 1950. In 1962, group 6 represented 2.7 percent of the countries but held only 22.4 percent of the total trade. The United States exports decreased from 20.3 percent of the total exports in 1950 to 17.6 percent in 1962. Imports decreased from 19.4 percent of the world total in 1950 to 16.6 percent in 1962.¹⁹ Canada's share of total exports and imports declined from 6.9 and 6.7 percent in 1950 to 5.4 and 5.3 percent respectively in 1962.

Groups 3 and 4 experienced an increase in their percentage share of total trade. These two groups received a constantly increasing percentage of the total trade in each of the four years examined, (Table 10). The percentage share of group 5 remained relatively constant over the period.

The overall results of the above changes led to a small increase in the index of concentration. This would indicate that the less developed countries have experienced a slightly smaller share of world trade. However, the change is very slight and therefore, doesn't substantiate the view that the divergency between the developed and less developed countries is rapidly widening.

¹⁹This information is contained in Appendix II.

Comparison of the United States
With Each of the Per Capita
Income Groups

The distribution of gross national product, exports, imports, and total trade of the per capita income groups of countries, except for group 6 of which the United States was a part, was compared to the United States. This gives an indication of the changes in inequality between the per capita income groups and the United States. A decrease in inequality with respect to income or trade would indicate a convergence of the economy of the United States and the other group. It is assumed that this would be desirable especially for the groups with low per capita incomes.

Table 12 gives the index of concentration for the distribution of gross national product, exports, imports and total trade for the comparison of the United States to each of the other groups. The inequality in the distribution of gross national product between the United States and the other groups decreased over the 1950-1962 period in all groups except group 1. The inequality between the United States and group 1 increased slightly. These changes can be seen by examining the concentration curves of Plate IV.

The inequality in the distribution of total trade between the United States and groups 3, 4, and 5 decreased over the thirteen years. The inequality between the United States and group 2 remained fairly constant. The inequality between the United States and group 1 increased.

PLATE IV

Figure 9

Figure 10

Figure 11

Figure 12

Figure 13

The inequality in the distribution of exports and imports between the United States and each of the other groups decreases, with the exception of group 1, for the period, 1950-1962. The inequality between the United States and group 1 with respect to exports increases slightly. The implications of these results indicate that there has been a convergence between the economies of the United States and each of the other groups with the exception of group 1.

To summarize this chapter it is evident from viewing the concentration curves and indices that there has been no increase in inequality in the distribution of gross national product between the developed and less developed countries under any method of grouping. On the basis of the concentration curves and indices it was concluded that there was not sufficient evidence to substantiate the view that there is an increasing divergency between the developed and less developed countries with respect to the distribution of trade.

CHAPTER IV

CHANGES IN INEQUALITY OF GROSS NATIONAL PRODUCT, EXPORTS, IMPORTS AND TOTAL TRADE AMONG REGIONS OF THE WORLD

A procedure of analysis, often followed for making comparisons, is to discuss countries by regions of the world. Therefore, it would seem beneficial to examine these regions and the inequality and changes in inequality which have occurred in the distribution of gross national product, exports, imports and total trade.

The regions examined were the English and European speaking countries - group 1; the Latin American countries - group 2; the Middle Eastern countries - group 3; the Asian countries - group 4; and the African countries - group 5.¹⁹ A list of the countries in each group is contained in Appendix IV.

Table 13 gives the distribution of gross national product, exports, imports and total trade for the regions. By examining the indices of concentration it is possible to get an idea of the changes in inequality which have taken place between the regions over the period, (1950-1962). The concentration curves for these distributions are shown in Plate V.

¹⁹The country classification of these groups was taken from: (C. Wilcox, W. Weatherford and H. Hunter, op. cit.).

^aSource: Derived from Appendices II and V.

Table 14 shows that the index of concentration for the distribution of gross national product was the same in 1962 as it was in 1950. However, the index shows a gradual increase in inequality for 1954 and 1958, which had declined by 1962. Although there probably existed a slight increase in inequality for this interperiod, the increase was not as large as the index indicates. The reason for this is that the distribution for 1958 included a larger number of countries than the distribution for 1950. These additional countries were either newly formed or in general the poorer countries and had only recently made data available. If data for these countries had been included in the 1950 distribution, it is doubtful whether there would have been any significant increase in inequality in the interperiod. As explained earlier, this tends to make group 1, which has over

TABLE 14. -- Index of concentration for the distribution of gross national product, exports, imports and total trade for countries grouped by regions of the world.^a

Figure 14

Figure 15

percentage of gross national product held. The result is an exaggeration of the actual inequality when comparing the 1958 distribution to 1950.

A close examination of Figure 14 shows that in 1962 there was a tendency towards an increase in inequality in the distribution of gross national product due to the English-European countries, which was balanced out by a tendency toward a decrease in inequality by the Latin American countries. Therefore, there was no change in the concentration index over the period for 1950 and 1962.

The index of concentration for the distribution of total trade, exports and imports shows a slight increase in inequality. Here again the index is overstated for the year 1958. The overall increase is apparent in Figure 14 where the concentration curve shows greater inequality in all cases. Figure 15 shows the concentration curves for the distribution of exports and imports. These curves reflect the increase in inequality which was shown in the distribution of total trade. The concentration indices increased from .434 in 1950 to .525 in 1962 for exports. The concentration indices increased from .468 in 1950 to .519 in 1962 for imports.

Comparison of the English Speaking
and European Countries with each
of the Other Regions

The distribution of gross national product, exports, imports and total trade of the regions was compared to the English Speaking and European Countries for the period, (1950-1962). This gives an indication of the changes in inequality between the English Speaking and European countries and the other regions. Table 15 gives the indices of concentration for this comparison of gross national product, exports, imports and total trade.

The indices of concentration for the distribution of gross national product shows that there was very little tendency towards an increase in inequality between the English-European countries and all other groups. There was a slight increase in inequality between the English-European countries and Africa. The relation of the English-European countries to the Middle Eastern and Asian countries was about the same over the period. The relative good performance of the Asian countries was due to the high large values of gross national product for India and Japan.

In the distribution of total trade there was a small tendency towards increasing inequality between the English-European countries and the Middle Eastern and African countries. There was very little change in the Latin American countries and a slight increase in inequality between the English-European

^aSource: Derived from Appendices II and V.

countries and the Asian countries. This same pattern is present in the distributions for exports and imports with no other significant variations.

The major conclusions are that the slight increase in inequality in the distribution of gross national product, exports, imports and total trade compared to the English-European countries is most prevalent in the case of the African countries. There was very little change in inequality for the Asian and Middle Eastern countries with Latin America remaining fairly constant with respect to the distribution of total trade, exports and imports. Latin American countries compared to the English-European countries experienced a decline in inequality in the distribution of gross national product.

Changes in the Inequality of the
Distribution of GNP, Exports, Imports
and Total Trade Within the Regions
of the World

Each countries share of the total gross national product, exports, imports and total trade within each region was arranged in ascending order and grouped by quintiles (Table 16), for 1950 and 1962.

The top quintile of countries within the English-European group of countries experienced a decline in the percentage share of gross national product, exports, imports and total trade over the period, 1950-1962. The lowest quintile experienced an

^bTrade is the sum of exports and imports of goods and services.

increase from 0.77 to 0.80 percent in its share of gross national product, but experienced a decline in its share of total trade. This decrease in total trade was due to a decline in the percentage share of exports while the share of imports remained constant. However, an increase in the share of both gross national product and trade for the second, third and fourth quintiles along with a decrease in the top quintiles share resulted in a decrease in the overall inequality within the group of English-European countries. Table 17 shows the index of concentration for the distribution of gross national product, exports, imports and total trade. There is a consistent decline in inequality over the period.

The Latin American countries followed almost exactly the same pattern as the English-European countries, except that the lowest quintile of the Latin American countries increased its percentage share of total trade. However, this increase in total trade appeared to be due to an increase in imports not exports. The lowest quintile of the Latin American countries experienced a decline in its percentage share of gross national product. The overall result was a decrease in inequality within the group of Latin American countries in the distribution of gross national product, exports, imports and total trade, (Table 17).

The inequality within the group of Middle East countries decreased with respect to the distribution of exports, imports and total trade. There was an increase in inequality in the

^aSource: Derived from Appendices I, II and V

distribution of gross national product, which resulted from the lowest quintiles percentage share declining while the top quintiles increased, (Table 16).

The general tendency within the Asian group of countries for the distribution of gross national product, exports, imports and total trade was towards increased inequality. The lowest, second and top quintiles increased their share of gross national product, while the third and fourth quintiles experienced a decline. The result, due mainly to the large increase in the top quintiles share of gross national product, was an increase in inequality. The increase in inequality in the distribution of total trade was due mainly to the decline in percentage share of exports of the second and third quintiles.

The largest change in inequality within the African group of countries occurred in the distribution of gross national product. A large part of this increased inequality was due to the decline of the percentage share of gross national product in the lowest quintile. The inequality in the distribution of total trade and imports remained rather constant over the period. There was an increase in inequality in the distribution of exports due mainly to a decline in the percentage share of the lowest, third and fourth quintile. The top quintile experienced an increase in its percentage share of exports.

As has been generally true throughout this study there exists greater inequality in the distribution of gross national product within these regions than there was in the distribution of either exports, imports or total trade. Likewise, as would

be expected the greatest inequality existed within the English-European group of countries. The reason for this large inequality is that this group covers a wide range of countries. It includes large countries like the United States as well as smaller countries like Ireland. The inequality within this group would be reduced greatly by removing the United States from the group.

The region with the least inequality in the distribution of gross national product, exports, imports and total trade is the Middle East.

Dominance of Countries Within Each Region

Although an examination of inequality and its changes has been made, no mention has been made of the countries responsible for these changes. Some insight to this situation can be gained by examining the top four countries in each region and their share of gross national product, exports and imports over the period, 1950-1962.

The top four countries of the English-European group of countries consisted of the United States, United Kingdom, France and Germany in 1962. The only difference in 1950 was that Canada had the fourth highest percent of exports and imports. The percentage share of gross national product held by these top four countries declined from 80.9 percent to 79.4 percent. However, the decline in the percentage of exports and imports was much greater. This indicates that the pattern of dominance in the English-European group has changed very little, (Table 18).

TABLE 18. -- Changes in the share of gross national product, exports and imports of the top four countries in each group for 1950 and 1962.^a

	1950			1962		
	Top Four Countries	Percentage		Top Four Countries	Percentage	
	GNP	Exports	Imports	GNP	Exports	Imports
Group 1	80.9	64.4	60.2	79.4	57.8	56.5

Group 3	82.8	86.0	77.0	76.9	74.2	71.0
Group 4	91.4	75.7	77.7	87.8	81.3	77.2
Group 5	79.1	84.0	77.7	72.6	72.9	69.0

^aSource: Derived from Appendices I, II and V.

The top four countries of the Latin American group consisted of Argentina, Brazil, Mexico and Venezuela in 1950. The only change in composition in 1962 was the replacement of Brazil by Puerto Rico for exports and imports only. There was very little change in the percentage share of gross national product held over the period. The percentage share of imports declined in 1962. Earlier indications were that Latin America and the English-European countries experienced a decrease in inequality in the distribution of gross national product. It is evident that this decrease in inequality was not at the expense of the top four countries in either group. However, a large portion of the decrease in inequality in the distribution of exports and imports can be attributed to the top four countries in both groups.

The top four Middle Eastern countries in 1950 were Algeria, Morocco, Turkey and Egypt. In 1962, Israel replaced Algeria as

the fourth country in gross national product and imports. Iraq replaced Algeria as the fourth country in exports. Their percentage share of gross national product decreased from 82.8 percent in 1950 to 76.9 percent in 1962. However, the overall inequality in the distribution of gross national product increased during this period. The decline of the top four countries percentage share of exports and imports resulted in a decrease in inequality in the distribution of exports and imports in the Middle East.

The top four Asian countries were India, Japan, Pakistan and the Philippines for the distribution of gross national product in 1950, but Indonesia replaced the Philippines for the fourth country in the distribution of exports and imports. The top four countries in Asia were responsible for the increase in inequality in the distribution of exports. The exports of the top four countries increased from 75.7 percent to 81.3 percent. Japan's exports increased from 26.0 percent in 1950 to 48.0 percent of the total Asian exports in 1962.

The top four African countries in 1950 were Ghana, Nigeria, Rhodesia and Nyasaland and Congo (D.R.). In 1962 Sudan replaced the Congo as the fourth country. The top four countries percentage shares in Africa declined. However, the effects of this decline have been less profound since the absolute inequality isn't too large in Africa. This means that the top four countries are not as distinctly dominant as the top four in the other groups with the possible exception of the Middle East.

CHAPTER V

SUMMARY AND CONCLUSIONS

This study set out with the object of examining the inequalities in international trade among eighty-five free market countries of the United Nations for the thirteen year period, (1950-1962). Since comparisons were involved, it became necessary to have some measure of economic activity of nations. The measure chosen, because it is the most widely used and easiest to obtain, was the gross national products of the countries. This data along with the trade data for all the countries was converted into United States dollars at 1960 prices.

It was concluded that it would be difficult to devise a complete measure of the actual inequality among nations. The Lorenz curve and the concentration ratio principle are used in this study to compare inequality among nations and changes which have occurred in inequality over a period of time.

The volume and trends in total trade, gross national product and population were examined. The world economy has exhibited substantial growth in both gross national product and total trade.

An examination of changes in inequality in the total distribution of gross national product, exports, imports and total trade was made for the period, 1950-1962. It was found that there has been no increase in inequality in the distribution of gross national product for the overall distributions of the

countries. In fact, there has been a slight decrease in inequality. The index of concentration for the distribution of total trade increases from .721 in 1950 to .729 in 1962, indicating almost no change in inequality.

The countries were divided into quintiles and attempts were made to assess the changes in inequality among the distributions of exports and imports. The slight increase in inequality in the distribution of exports and imports did not occur in the two lowest quintiles of countries. This was encouraging since a high correlation was found between countries with high incomes and trade. This finding would appear to have some implications to the developing countries.

The value of trade as a proportion of gross national product was examined and found to be an increasing ratio. The meaning of this increase can be interpreted several ways, but it would seem to imply an increasing dependence between countries of the world.

After examining the overall distributions, attention was focused on changes in inequality between the developed and less developed countries. There was no significant evidence of any increase in inequality in gross national product between the developed and less developed countries. However, there was a small increase in the index of concentration for distribution of trade between the developed and less developed countries. This would tend to indicate that there was some unfavorable changes towards the less developed countries with respect to trade.

A more explicit division of the developed and less developed countries was made by grouping them into per capita income classes. Again there was a slight downward trend in inequality between the groups in the distribution of gross national product. As before there was also a slight increase in inequality in the distribution of trade.

Each of the per capita income groups was compared to the United States. The inequality between the United States and the other groups decreased over the 1950-1962 period in all groups except the lowest per capita income group. The inequality in the distribution of total trade between the United States and per capita income groups three, four, and five exhibited a downward trend over the thirteen years. The inequality between the United States and groups one and two remained almost the same.

Since countries are often discussed in terms of regions of the world, it was felt beneficial to discuss the inequalities between and within these regions over the period, (1950-1962). The regions examined were the English-European, Latin American, Middle East, Asian and African countries. The results reveal little evidence of any increase in overall inequality in the distribution of gross national product between the regions. However, there was a slight increase in inequality in the distribution of trade.

The distribution of gross national product, exports, imports and total trade of the regions was compared to the English Speaking and European countries. There was no tendency

towards an increase in inequality between the English-European countries and the other regions, with the exception of Africa, for the distribution of gross national product. The inequality in the distribution of gross national product between the English-European countries and the Middle Eastern and Asian countries showed almost no change over the period. With respect to trade there was a greater tendency towards inequality between the English-European countries and the Middle Eastern and African countries. There was very little increase in inequality between the English-European countries and the Asian countries.

The inequality in the distribution of gross national product, exports, imports and total trade of the countries within each region was examined. The English-European countries and Latin America experienced a consistent decline in inequality for the distribution of gross national product, exports, imports and trade. The inequality within the Middle Eastern countries decreased with respect to the distribution of exports, imports and total trade but increased with respect to gross national product. The general tendency within the Asian region was for an increase in inequality in all distributions. The African countries experienced an increase in inequality especially in the distribution of gross national product and exports. One of the major consistencies for the study has been that the inequality in the distribution of gross national product has been greater than that for trade. The largest inequality within the

regions was exhibited by the English-European countries. The region with the least inequality within is the Middle East.

To examine the dominance of countries within each region the top four countries of each region were considered. In general there was very little change within the regions of the dominant countries over the period. However, the dominance of the top four countries in the Middle East and Africa was not as distinct as the other groups.

In conclusion, there is no evidence of any significant increase in inequality in the distribution of gross national product in any case. Whether it be between the developed and the less developed countries or the regions, there was no increased inequality. There was a general tendency for the inequality in the distribution of exports, imports and total trade to increase slightly among the different methods of grouping. However, the hypothesis that there has been any large increase in inequality between the developed and the less developed countries is questionable.

INEQUALITIES IN INTERNATIONAL TRADE
AMONG DEVELOPING NATIONS

by

HENRY MERLIN HAYS, JR.

AN ABSTRACT OF A MASTER'S REPORT

submitted in partial fulfillment of the

requirements for the degree

MASTER OF ARTS

Department of Economics

KANSAS STATE UNIVERSITY
Manhattan, Kansas

1968

The purpose of this report was to examine inequalities in the distribution of gross national product, exports, imports and total trade among eighty-five free market countries of the United Nations for the period, 1950 to 1962. The major concern is the purported divergency in income and trade between the developed and the less developed countries. An attempt was made to measure this divergency to see if the "gap" between the developed and the less developed countries is actually becoming greater.

To measure this divergency, the income and trade data of the countries was converted into United States dollars at 1960 prices. This provided a standard with which comparisons were made. The Lorenz curve concentration ratio was then used as a measure of inequality.

An examination of changes in inequality in the overall distribution of gross national product, exports, imports and total trade was first made. It was found that there has been no significant increase in inequality in the distribution of income or trade for the overall distribution of countries. This in itself is significant; however, it reveals very little about the changes that may have taken place between the developed and the less developed countries.

The countries were divided into a group of developed and a group of less developed countries and the changes in inequality were examined. There was no evidence of any increase in inequality between the developed and less developed countries in

the distribution of income. There was a slight increase in inequality in the distribution of trade. A more explicit division of the countries by per capita income classes was then made. The index of concentration exhibited a downward trend for the distribution of income, while the index for trade was almost the same.

A comparison was made between the United States and each of the per capita income groups. There was no increase in inequality between the United States and any of the per capita groups for either the distribution of income or trade. In fact, there was a downward trend in inequality for all groups except the lowest per capita income group.

An examination was made of inequality and changes in inequality in the distribution of income and trade for the different regions of the world. There was no significant change in inequality in the distribution of income for the regions. However, there appeared to be a slight increase in inequality in the distribution of trade. Results of comparisons of the English and European countries with each of the other groups showed no increase in inequality with the possible exception of Africa. An examination of inequality and changes in inequality within these regions was also made.

In general, the results of this study would tend to substantiate the view that the income and trade gap between the more developed and the less developed countries is not widening.
